

# 2D Graph Visualization

---

Node-Link Diagrams · Adjacency Matrices · Layout Algorithms · Hybrid Systems

**Raz Saremi, Ph.D.**

Tandon School of Engineering, NYU

**Information Visualization**

# What is a Graph? $G = (V, E)$

*Formal definition with real-world examples.*

## Formal Definition $G = (V, E)$

**V** Set of Vertices (Nodes)

**E** Set of Edges (Links)

**|V|** Number of nodes

**|E|** Number of edges

## 5-Node Undirected Graph

## Real-World Examples

- Social networks (people → friends)
- The Internet (servers → routers)
- Software systems (modules → deps)
- Biological networks (genes → proteins)

# The Challenge of Scale: Small vs. Large Networks

Max Possible Edges =  $n(n-1) / 2$

| Nodes | Max Possible Edges |
|-------|--------------------|
| 10    | 45                 |
| 50    | 1,225              |
| 100   | 4,950              |
| 500   | 124,750            |
| 1,000 | 499,500            |

## Small Networks (< 100 nodes)

- Density < 0.3 typically
- Node-Link works well
- Interactive exploration feasible

## Large Networks (> 100 nodes)

- 100k+ edges possible
- "Hairball" effect emerges
- Adjacency Matrix scales better

**Key Insight:** The right visualization depends on network size AND density.

# Visualization Goals: Readability, Pathfinding & Cluster Detection

## Readability

Minimize edge crossings and node overlaps. Text labels must remain legible at target zoom level.

## Path-finding

Can a user trace a route from A to B? Critical for network navigation and traversal tasks.

## Cluster Detection

Densely connected node groups should be visually separable from other communities.

## Outlier Spotting

Isolated nodes and bridge edges that connect separate components must visually stand out.

# Overview: The Two Main Paradigms

Every graph visualization uses one of these two foundational approaches.

Node-Link Diagram

## Node-Link Diagram (NL)

Nodes as circles, edges as lines. Intuitive & familiar metaphor. Best for sparse graphs below ~200 nodes.

Adjacency Matrix (AM)

|   | A | B | C | D | E |
|---|---|---|---|---|---|
| A |   |   |   |   |   |
| B |   |   |   |   |   |
| C |   |   |   |   |   |
| D |   |   |   |   |   |
| E |   |   |   |   |   |

No edge crossings — every edge is a filled cell. Ideal for dense/large graphs.

Choosing between NL and AM is the core decision in graph visualization. It depends on size, density, and the user's task.

# Anatomy of a Node-Link Diagram

*Understanding the visual vocabulary of node-link graphs.*

Anatomy of a Node-Link Diagram

## Hub / High-degree node

Many connections. Visually central in force-directed layouts.

## Leaf node

Only one connection. Found at graph periphery.

## Bridge edge

Single edge whose removal disconnects the graph.

## Isolate

Node with zero connections — no edges at all.

## Regular node

Average degree. Encodes data via size and color.

# Anatomy of an Adjacency Matrix

Reading a matrix — rows are sources, columns are targets.

|   | A | B | C | D | E | F |
|---|---|---|---|---|---|---|
| A |   |   | 1 |   | 1 |   |
| B | 1 |   |   | 1 |   |   |
| C |   | 1 |   |   |   |   |
| D | 1 |   |   |   | 1 |   |
| E |   | 1 |   | 1 |   | 2 |
| F |   |   | 1 |   |   |   |

**Diagonal = self-loops**

Nodes connected to themselves

**Filled cell = edge**

Nodes connected to themselves

**Row sum = degree**

Count filled cells in each row

**Diagonal = self-loops**

Empty in simple graphs (no self-connections).

**Filled cell = edge**

Cell (A,B) filled → edge A→B exists.

**Symmetric = undirected**

If  $(A,B) = (B,A)$ , the graph is undirected.

**Asymmetric = directed**

Different values at (A,B) vs (B,A) → digraph.

**Row sum = degree**

Count filled cells in a row to get node degree.

# Key Metric: Graph Density

Density governs which representation to choose.

Density =  $2|E| / (|V| \times (|V| - 1))$  for undirected graphs

Rule of Thumb

- NL if density < 0.3
- AM if density ≥ 0.3

Density vs Node Count

| Nodes | Sparse ( $ E = V $ ) | Dense ( $ E = V ^2/4$ ) |
|-------|----------------------|-------------------------|
| 10    | 0.22                 | 1.00                    |
| 50    | 0.04                 | 0.98                    |
| 100   | 0.02                 | 0.99                    |
| 200   | 0.01                 | 0.99                    |

# Why Layout Matters: Same Data, Different Perception

Same 11-node graph — random positions vs. force-directed spring layout.

**BAD Layout - Random Positions**  
Clusters invisible, edges cross everywhere

**GOOD Layout - Force-Directed**  
Clusters visible, paths traceable

# Edge Crossings

*How visual design choices directly affect task performance and accuracy.*

**85%**

Edge Crossings — increase in task time vs clean layout

**75%**

Node Overlaps — increase — labels hidden, grouping broken

**65%**

Unfamiliar Layout — increase — users struggle with non-standard arrangements

**55%**

Missing Labels — increase — identification tasks suffer most

**45%**

Excessive Color — increase — more than 7 hues overwhelms

*% increase in task-completion time vs. clean layout — Adapted from Purchase et al. 2002*

# Introduction to Force-Directed Layouts

*The most widely-used algorithm for general graph drawing.*

*Algorithms: Fruchterman-Reingold · ForceAtlas2 · D3-force*

## How It Works

### Charged particles

Nodes repel each other like electric charges

### Spring edges

Edges attract connected nodes like springs

### Repulsion

Keeps nodes apart; prevents overlap

### Equilibrium

Simulation ends when net force  $\rightarrow 0$

### Topology

Spatial proximity reflects graph structure

# Physics of Force-Directed: Hooke's Law & Coulomb's Law

## Spring Forces — Hooke's Law

$$F_{\text{spring}} = -k \cdot (d - L_0)$$

$k$  = spring stiffness constant

$d$  = current edge length

$L_0$  = ideal (rest) length

Connected nodes attract like springs. Edge length converges to ideal  $L_0$ .

## Repulsion — Coulomb's Law

$$F_{\text{rep}} = k_r / d^2$$

$k_r$  = repulsion constant

$d$  = distance between nodes

Every node pair repels like electric charges. Prevents overlaps.

Equilibrium: net force on all nodes  $\rightarrow 0$  — Layout stabilizes when attractive and repulsive forces balance.

Used in: D3.js forceLink · Gephi Yifan Hu · ForceAtlas2

# Force-Directed: Advantages & Community Structure

## Strengths

- Reveals community structure automatically
- No manual layout required
- Topological proximity maps to spatial distance
- Symmetric graphs → symmetric layouts
- Widely supported: D3.js, Gephi, Cytoscape, yED

## Limitations

- Slow:  $O(n^2)$  per iteration
- Non-deterministic results
- Hairball > 200 nodes
- Axis position has NO meaning

## Best Use Cases

Social networks · Knowledge graphs · Citation networks · Exploratory analysis

# Hierarchical Layouts: Visualizing Directed Acyclic Graphs (DAGs)

A DAG has direction but no cycles — perfect for hierarchies, pipelines & dependency trees.

DAG — Sugiyama Layered Layout (edges always flow top -> bottom)

## Sugiyama Layered Layout — Key Concepts

### Layered ranks

Nodes assigned to horizontal layers — edges always flow top-to-bottom.

### Crossing minimization

Barycenter heuristic reorders nodes to reduce edge crossings.

### Use cases

Git history, CI/CD pipelines, org charts, build systems.

### Libraries

Dagre.js · ELK · Graphviz dot

# Top-Down vs. Left-to-Right Flows in Trees

Same binary tree (depth 3) drawn with two different layout orientations.

**Top-Down (TB)**  
Org charts, family trees

**Left-Right (LR)**  
Pipelines, decision flows

# Radial Layouts: Focusing on Centrality & Symmetry

Root node at center; distance from center = graph depth.

**Radial Layout** — Distance from center = hierarchy depth  
Root (gold) -> L1 (teal) -> L2 (navy)

## Center = root

Root placed at the center origin.

## Depth = radius

Distance from center encodes graph depth.

## Angular position

Subtree identity encoded angularly.

## Concentric rings

Each ring shows one hierarchy level.

## Ego-networks

Natural fit — spotlight on one node's neighborhood.

## Tools

Gephi · yED · Cytoscape

# Radial Layouts for Large Hierarchies: Sunburst & Circle Packing

Both encode hierarchy using 2D space — ideal for showing large trees compactly.

## Sunburst Chart

Inner ring = L0, outer rings = deeper levels (arc length = proportion)

## Circle Packing

Containment = parent-child (circle area = value)

# Arc Diagrams: Linear Ordering & Longitudinal Paths

*Nodes on a baseline; arcs encode connections above/below.*

**Arc Diagram — Nodes on a line, arcs encode connections  
(Arc height  $\propto$  distance between nodes)**

## Proas

- No node overlap — ever
- Long-range patterns clearly visible
- Works with meaningful ordering
- Natural linear timeline fit

## Cons

- Arc crossings increase with density
- Hard to encode node attributes
- Requires meaningful ordering
- Confusing when nodes > 50

# Case Study: Arc Diagrams for Software Dependencies

12 JavaScript modules in load-sequence order — 15 import dependencies visualized as arcs.

**Software Module Dependencies — 12 modules, 15 dependency arcs**  
Long arcs = transitive deps (tight coupling warning!)

Long arcs reveal transitive dependencies skipping layers — a sign of tight coupling. Tool: Observable Plot · D3 arc · Gephi Arc Layout plugin

# Circular Layouts: Simple but Prone to Crossover Clutter

*Nodes on a circle — clean for small graphs, problematic when dense.*

**Circular Layout — Equal-status nodes on a circle**  
**Chord edges (red dashes) increase crossings**

— Cycle edges -- Chord edges (create crossings!)

## When Circular Works

- Small number of nodes ( $< 20$ )
- All pairwise comparisons equal
- Chord diagrams (weighted edges)
- No inherent hierarchy

## Circular Pitfalls

- Chord crossings grow as  $O(n^2)$
- No structural info in position
- Axis position is arbitrary
- Hides community structure

# Summary Table of Layout Techniques

Choose the layout that matches your data structure and user task.

| Layout             | Best For                         | Scalability         | Key Weakness                |
|--------------------|----------------------------------|---------------------|-----------------------------|
| Force-Directed     | General exploration, social nets | ~1K nodes           | Hairball; non-deterministic |
| Hierarchical (DAG) | Pipelines, org charts, CI/CD     | High (with pruning) | Requires strict DAG         |
| Radial             | Ego-networks, centrality         | ~500 nodes          | Overcrowding at outer rings |
| Arc Diagram        | Ordered sequences, timelines     | High (linear axis)  | Crossing arcs when dense    |
| Circular           | Small equal-status sets          | < 30 nodes          | Reveals no structure        |
| Adjacency Matrix   | Dense, large graphs              | 10k+ nodes          | Pathfinding difficult       |

# Visual Exercise: Identifying the Best Layout

Discuss with a neighbour: which layout best fits each scenario, and why?

**Family Tree**  
-> Hierarchical Layout

**Social Network**  
-> Force-Directed

**Protein Network**  
-> Adjacency Matrix

**Sequential Data**  
-> Arc Diagram

PART 3

# Node-Link Diagrams

---

*Strengths, weaknesses, and when they work — and when they don't*

# When to Choose Node-Link: Small & Sparse Data

Rule:  $|V| < 100$  AND  $Density < 0.3 \Rightarrow$  Node-Link is your friend

**Hop Count vs. Spatial Distance  
in Force-Directed Layout (r=0.91)**

**Spatial Proximity Reflects Topology  
Force-directed layout — topology -> position**

# The Weakness: The "Hairball" Phenomenon

*When node-link exceeds ~200 nodes it degrades into unreadable tangles.*

**GOOD: 50 nodes (BA model, sparse)**  
**Readable — clusters & hubs visible**

**BAD: 300 nodes (ER random graph)**  
**"Hairball" — structure unreadable!**

# Visual Clutter: Edge Crossings & Node Overlaps

Purchase 1997 — error rate scales super-linearly with crossing count.

| Crossings     | Avg Error Rate (%) |
|---------------|--------------------|
| 0 crossings   | 5%                 |
| 5 crossings   | 12%                |
| 10 crossings  | 24%                |
| 20 crossings  | 38%                |
| 40+ crossings | 67%                |

## Edge Crossings

Ambiguity due to overlapping connections. Are these paths connected or just crossing?

## Node Overlaps

Crowded nodes are overlapping and labels are hard to read.

## Node Overlaps

Crowded nodes are overlapping and labels are hard to read.

# Scalability Limits: Where Node-Link Starts to Fail

*NL readability score degrades sharply after ~100 nodes.*

| Node Count | NL Readability | AM Readability |
|------------|----------------|----------------|
| 10         | 95             | 60             |
| 50         | 82             | 70             |
| 100        | 70             | 75             |
| 200        | 45             | 78             |
| 500        | 20             | 82             |
| 1,000      | 8              | 85             |
| 5,000      | 2              | 88             |

## Key Insight

NL and AM have opposite scalability curves — they are complementary tools.

Below 100 nodes: NL dominates.

Above 100 nodes: AM is consistently more readable.

Hybrid approaches bridge the gap.

# Use Case: Local Neighborhood Analysis (Ego-Networks)

Ego-network: focus on one node and its 1- or 2-hop neighbors. NL is ideal.

**Ego-Network Analysis — 2-hop neighborhood**  
Gold = ego, Navy = 1-hop, Blue = 2-hop

## Applications

|                                |
|--------------------------------|
| Twitter follower analysis      |
| Citation network of a paper    |
| Friend-of-friend in LinkedIn   |
| Network security: blast radius |
| Drug interaction neighbors     |
| Customer influence mapping     |

## NL Best Practices: 6 Techniques to Reduce Visual Clutter

## Node Color = Community

Categorical color encodes cluster membership.  
Use max 8 distinct hues.

## Node Size = Degree

Larger nodes signal higher degree. Hub nodes stand out without labels.

## Edge Bundling

Group parallel edges into bundles. Reduces visual noise by 40–70% in dense graphs.

## Edge Width = Weight

Thicker edges signal stronger relationships. Prune edges below threshold.

## Semantic Zoom

Show labels at high zoom; cluster blobs at low zoom. Prevents overload.

## Degree Filtering

Slider removes nodes below degree threshold.  
Exposes core structural skeleton.

PART 4

# Adjacency Matrix Representations

---

*Moving from links to grids*

# Why AM is Immune to Edge Crossings

*In an AM every edge is a filled cell — there are NO lines to cross, EVER.*

**BAD: Node-Link ( $K_6$  complete graph)**  
15 edges -> many crossings, hard to read

**GOOD: Adjacency Matrix ( $K_6$  complete graph)**  
15 edges -> zero crossings, instantly readable

|   | A | B | C | D | E | F |
|---|---|---|---|---|---|---|
| A |   | 1 | 1 | 1 | 1 | 1 |
| B | 1 |   | 1 | 1 | 1 | 1 |
| C | 1 | 1 |   | 1 | 1 | 1 |
| D | 1 | 1 | 1 |   | 1 | 1 |
| E | 1 | 1 | 1 | 1 |   | 1 |
| F | 1 | 1 | 1 | 1 | 1 |   |

# AM Scalability: Visualizing Thousands of Nodes in a Single View

| View Mode   | NL Max Readable | AM Max Readable |
|-------------|-----------------|-----------------|
| With labels | 50              | 100             |
| No labels   | 150             | 2,000           |
| Bundled     | 300             | 2,000           |
| Clustered   | 800             | 10,000          |

## Why AM Scales Better

Each row/column is a fixed-width strip. Adding 1,000 nodes adds 1,000 strips — not 1,000 overlapping circles. Pixel-level rendering shows 10,000+ nodes in a single view.

# Detecting Clusters: The Importance of Matrix Reordering

Reordering rows/columns groups connected nodes into visible block-diagonal patterns.

Before Reordering

After Reordering (Seriation)

Clique = all cells in block filled

Block size = clique size  $k$

Multiple cliques = diagonal block pattern

Overlapping = shared rows/columns

Seriation algorithms: Reverse Cuthill-McKee · Spectral ordering

# Patterns in Matrices: Finding Cliques (Solid Blocks)

A clique is a fully connected subgraph — it appears as a solid filled square along the diagonal.

Clique = all cells filled

Block size = clique size  $k$

Multiple cliques = diagonal blocks

Overlapping = shared rows/cols

Applications: fraud rings · protein complexes · social cliques · research collaborations

# Patterns in Matrices: Bridges & Off-Diagonal Connections

Off-diagonal cells reveal inter-cluster connections — bridge nodes linking separate communities.

### Off-diagonal isolated cells

Weak ties — occasional connections between clusters.

Multigraph

|   | A | B | C | D |
|---|---|---|---|---|
| A | 0 | 1 | 0 | 1 |
| B | 1 | 0 | 0 | 1 |
| C | 0 | 0 | 0 | 2 |
| D | 1 | 1 | 2 | 0 |

### Off-diagonal bands

Structured coupling between two groups.

Adjacency matrix

|   | 1 | 2 | 3 | 4 | 5 |
|---|---|---|---|---|---|
| 1 | 1 | 1 | 1 | 0 | 1 |
| 2 | 1 | 1 | 0 | 0 | 1 |
| 3 | 1 | 0 | 1 | 0 | 1 |
| 4 | 0 | 0 | 1 | 1 | 1 |
| 5 | 1 | 1 | 1 | 1 | 1 |

### Bridge nodes

Appear in multiple block rows/columns — connectors.

Bridge node Bridge edge

Community 1 Community 2

### Removing bridge

Disconnects the graph — critical vulnerability point.

Global bridge Local bridge

(A) (B)

Applications: supply chain vulnerabilities · social brokers · interdisciplinary collaboration networks

# AM Weakness: Difficult Pathfinding — The "Mental Hop" Problem

Each hop requires scanning a full row AND column — 2 axis changes per step.

## Mental Hop Procedure (A → D):

- 1 Step 1: Find row 'A' → filled at B, C
- 2 Step 2: Jump to col 'B' → find row B → filled at C, D
- 3 Step 3: D reached! 2 hops, 4 axis changes.

### Why This Matters

Each hop requires the user to:

- 1. Scan an entire row
- 2. Switch to the column header
- 3. Repeat

For a 4-hop path → 8 axis changes.  
Pathfinding in AM is a working memory workout.

Research: 3–4× longer than NL (Ghoniem et al. 2005)

| Task           | AM (sec) | NL (sec) |
|----------------|----------|----------|
| 2-hop path     | 8        | 5        |
| 3-hop path     | 22       | 9        |
| 4-hop path     | 45       | 14       |
| Cluster detect | 12       | 35       |
| Pattern ID     | 5        | 40       |

# AM Weakness: High Learning Curve for Non-Experts

~60% of non-expert users cannot correctly read a basic adjacency matrix without training.

| Expertise Level              | Success Rate (%) |
|------------------------------|------------------|
| Expert (no training)         | 92%              |
| After 5-min tutorial         | 85%              |
| After 15-min tutorial        | 88%              |
| Non-expert (no training)     | 38%              |
| Non-expert (30-min training) | 74%              |

Gibson et al. 2013

Design Mitigations

- Add row/column hover highlights
- Interactive tooltips on each cell
- Small NL overview alongside AM
- Use heatmap color not just 0/1
- Add clear legends & axis labels
- Consider MatLink hybrid approach

# Optimizing the View: Sorting by Degree vs. Community

How rows and columns are ordered determines what patterns become visible.

| Sort Strategy    | Best For                 | Visual Effect                        | Algorithm      |  |
|------------------|--------------------------|--------------------------------------|----------------|--|
| By Degree (desc) | Finding hubs & outliers  | Dense top-left → sparse bottom-right | Row sum sort   |  |
| By Community     | Cluster detection        | Block-diagonal structure             | Spectral / RCM |  |
| Alphabetical     | Lookup by name           | Predictable but structure-blind      | None           |  |
| By Betweenness   | Bridge identification    | High-BC nodes appear centrally       | Brandes O(VE)  |  |
| Random           | Showing reordering value | No structure — comparison baseline   | Math.random()  |  |

# NL vs. AM: Finding a Node vs. Finding a Pattern

*Different representations excel at fundamentally different cognitive tasks.*

| Task                 | Node-Link                   | Adjacency Matrix           |
|----------------------|-----------------------------|----------------------------|
| Find a specific node | Fast — direct visual search | Must scan all labels       |
| Trace a 2-hop path   | Follow edges visually       | Mental hop required        |
| Detect a cluster     | Only with good layout       | Solid diagonal block       |
| Count node degree    | Count edge lines            | Count filled cells in row  |
| Find global density  | No clear visual encoding    | Proportion of filled cells |
| Identify hub node    | Largest / most central      | Most filled row/column     |

# Head-to-Head: Small/Sparse vs. Large/Dense

A comprehensive comparison — choose the right tool for your data.

| Property          | Node-Link                   | Adjacency Matrix           |
|-------------------|-----------------------------|----------------------------|
| Best graph size   | < 100 nodes                 | 100 – 10,000+ nodes        |
| Best density      | Sparse (< 0.3)              | Dense (> 0.3)              |
| Edge crossings    | Common in dense graphs      | Impossible — by design     |
| Pathfinding       | Intuitive                   | Mental hops required       |
| Cluster detection | Moderate (layout dependent) | Excellent (block patterns) |
| Learning curve    | Low — familiar metaphor     | High — non-standard        |
| Key tools         | D3-force, Gephi, Cytoscape  | D3, Reorder.js, Observable |

# Task Efficiency: Pathfinding (NL) vs. Global Structure (AM)

Task success rate — Ghoniem et al. 2005.

PART 5

# Hybrid Approaches & Interactivity

---

*Combining the best of both paradigms*

# Hybrid Approaches: MatLink & NodeTrix

Overlay node-link and matrix representations to preserve the strengths of both.

**NodeTrix Hybrid** — Clusters shown as mini-matrices, inter-cluster edges as node-link  
Best of both: patterns (AM) + paths (NL)

## MatLink (Henry & Fekete 2006)

Matrix + arc diagram overlay. Arcs drawn outside matrix for key paths. Reduces mental hop burden.

## NodeTrix (Henry et al. 2007)

Dense clusters shown as matrices; sparse inter-cluster links as node-link edges. Best of both.

# Multi-View Systems: Linked Brushing Between NL and AM

Selecting nodes in NL instantly highlights their rows/cols in AM — and vice versa.

NL View — Select nodes A & B  
(gold = selected)

AM View — A & B rows/cols highlighted  
(linked brushing from NL selection)

|   | A | B | C | D | E | F |
|---|---|---|---|---|---|---|
| A |   | 1 | 1 | 1 | 1 | 1 |
| B | 1 |   | 1 | 1 |   |   |
| C | 1 | 1 |   | 1 |   |   |
| D | 1 | 1 | 1 |   |   |   |
| E | 1 |   |   |   |   |   |
| F | 1 |   |   |   |   |   |

# Zooming & Filtering: Interactive Graph Exploration

*Six interaction techniques that make large graphs navigable.*

## Semantic Zoom

Low zoom = clusters; high zoom = individual nodes/labels. Prevents overload at every scale.

<https://observablehq.com/@d3/force-directed-graph-component>

## Degree Filter

Slider removes nodes with degree < threshold. Exposes the core structural skeleton.

## Focus + Context

Fisheye distortion magnifies area of interest while keeping global view visible.

<https://bost.ocks.org/mike/fisheye/>

## Community Filter

Toggle entire communities on/off. Study one cluster in isolation.

<https://www.polinode.com/>

## Time Slider

For temporal networks: animate edge appearance/removal over time.

## Search + Highlight

Type node name → highlight node and neighbors; others fade to 20% opacity.

# Case Study: Biological Networks & Gene Expression

20,000+ genes and millions of interactions in the human proteome.

## Scale-free structure

Few hub proteins, many leaf nodes — power-law degree distribution.

## Hub proteins

Essential for cell survival — disrupting them is often lethal.

## AM + reordering

Reveals protein complexes as block-diagonal patterns.

## WGCNA modules

Gene co-expression: edge = Pearson correlation; modules = pathways.

## Tools

Cytoscape + STRING database · NetworkX · BioGRID

# Tools for Implementation: D3.js, Gephi, Cytoscape

Use the right tool for your data, audience, and skill level.

## D3.js

### Web-based NL+AM+Force

*Skill: Advanced (JS)*

Maximum customization, animations, linked views. Observable integration.

## Gephi

### Desktop NL exploration

*Skill: Beginner-friendly*

Modularity detection, ForceAtlas2, rich plugin ecosystem.

<https://gephi.org/>

## Cytoscape

### Biological/molecular

*Skill: Intermediate*

Biological DB integration (STRING, BioGRID), SBGN notation.

## Observable

### Notebook NL+AM

*Skill: Intermediate JS*

Reactive notebooks. Great for teaching and prototyping.

## NetworkX

### Python analysis

*Skill: Python users*

Algorithm library. Pairs with Matplotlib or D3 for rendering.

## Graphviz

### Static hierarchical

*Skill: Low*

dot/neato engines. Best for DAGs, dependency trees, CI/CD diagrams.

# Q & A + Final Review

---

*"No single representation is best for all tasks — combine views for complex analyses."*

Q: Which layout for a 500-node social network? → Force-directed + edge bundling, OR Adjacency Matrix if density > 0.3

Q: How do we detect cliques in large graphs? → Matrix reordering reveals solid diagonal blocks

Q: What is the main weakness of NL at scale? → The Hairball effect — edges tangle into unreadable messes

Q: Name one hybrid approach and its advantage. → MatLink / NodeTrix — preserves paths AND global patterns

Q: What density triggers the switch to AM? → Density > 0.3 OR node count > 100
